1 Introduction

1.1 Basic definitions

- Feature
 - Command: No return value, but does modify objects. On the synctactical level, it is an instruction
 - Query: Returns a value, but does not modify any objects. The syntax equivalent is the expression.
 - * Functions get their results through computation
 - * Attributes are values directly stored in memory

For queries, there is the uniform access principle, which states that it doesn't matter to the client whether a query is implemented as a function or attribute. Features should be accessible to clients the same way whether implemented by storage or by computation.

- Creation Procedure: Commands to initiate objects, can be several.
 There is also a default_create, which is inherited by all classes, and does nothing by default.
- Feature Calls
 - Unqualified calls: Feature calls which apply to the current object
 - Qualified calls: Feature calls which apply to a certain object, causing this object to become the current object.
- Class clauses
 - Indexing
 - Inheritance
 - Creation
 - Feature
 - Invariant
- Specimen: A syntactic element, such as a class name or an instruction, but no delimiters. The type of a specimen is its construct. See Describing syntax

Add reference

- Abstract syntax tree: Shows the syntax structure with all its specimens, but obviously without any delimiters, A tree has nodes, each one of the following kind:
 - Root: Node with no incoming branch.
 - Leaf: Node without outgoing branches
 - Internal node: Neither of the former
- Basic elements of a program text:
 - Terminals
 - * Identifiers: Names chosen by the programmer

- * Keywords
- * Special symbols, such as a period
- Describing a program
 - Semantic rules: Define the effect of programming, satisfying the syntax rules
 - Syntax rules: Define how to make up specimens out of tokens satisfying the lexical rules
 - Lexical rules: Define how to make up tokens out of characters
- Syntax: The way you write a program; characters grouped into words, grouped into bigger structures.
- Semantics: The effect you expect from this program at runtime
- Identifier: Name chosen by the programmer to represent certain program elements, such as classes, features or runtime values. If it denotes a runtime value, it is called an identity or variable if it can change its value. During execution, an entity may become attached to an object.
- Executing a system consists of creating a root object, which in an instance of a designated class from the system, the root class, using a designated creation procedure, called its root procedure.

1.2 Variables

- Types
 - Reference types: Entities with a reference value
 - Expanded types: Entities with an object as a value
 - A type is one of:
 - * A non-generic class
 - * A generic derivation, i.e. the name of a class followed by a list of types, the actual generic parameters, in brackets
- Setters: It is possible to make assignments such as x.att := val, which is shorthand for $x.set_att(val)$
- Effect of an assignment
 - Reference types: Reference assignment
 - Expanded types: Value copy
- Variable copy
 - Shallow object duplication (creates a new object): b := a.twin
 - Deep object duplication (creates a new object): $b := a.deep_twin$
 - Shallow field-by-field copy (does not create an object): b.copy(a)

Maybe add the objet creation diagram??

1.3 Interface

- A client of a software mechanism is a system of any kind such as a software element or a human that uses it. For its client, the mechanism is a supplier
- Interface: The description of techniques enabling clients to use these mechanisms. For example: GUIs (Graphical User Interface), command line interfaces (shell, bash,...), or APIs
- An object can be an instance of a class, if the class is the generating class of the object

1.4 Information Hiding

- For its clients, an attribute may be:
 - Secret
 - Read-only
 - Read, but partially write restricted (only certain things are allowed to be written)
 - Writing one or more classes in curly brackets after the keyword feature exports these features only to these classes and its descendants.
 If no class is listed, the features are exported to ANY.

Information hiding only applies to use by clients using dot or infix notation. Unqualified calls are not subject to information hiding.

1.5 Control structures

Requires a lot of work

- Sequence or compound
- Loop
 - Loop invariant
 - * Satisfied after initialization, after the from clause
 - * Preserved by every loop iteration executed with the exit condition not satisfied. So in the end, the loop invariant and the exit condition hold!
 - Loop variant
 - * Non-negative (i.e. $\geq 0)$ integer expression, right after initialization
 - * Decreases while remaining non-negative for every iteration of the body with exit condition not satisfied.
- Conditional

1.6 Contracts

- Contracts are made of assertions, each containing an assertion tag and a condition (a Boolean expression)
- Precondition
 - Property that a feature imposes on every client
 - If there is no require clause, is treated as one, with one only being true.
- Postcondition
 - Property that a feature guarantees every client
 - Can make use of keyword old
- Class invariant
 - The invariant expresses consistency requirements between queries of a class

Check for an explanation of this keyword

1.7 Miscellaneous

- Semistrict operators
 - Let us define the order of expression evaluation
 - and then is the semistrict version of and. Use it if a condition only
 makes sense when another is true.
 - or else is the semistrict version of or. Use it if a condition only makes sense when another is false
 - **implies** is always semstrict!

2 Describing syntax
